

On mean values of the zeta-function, II

by

J. B. CONREY and A. GHOSH* (Stillwater, Okla.)

In the study of the finer behavior of the Riemann zeta-function the problem of finding an asymptotic formula for

$$M(T) = \int_1^T |\zeta(1/2 + it)| dt$$

is of some interest. Ramachandra [6] has shown that $M(T)$ has order of magnitude $T(\log T)^{1/4}$. The present authors [2] have shown, assuming the Riemann Hypothesis, that

$$M(T) \geq T \sum_{n \leq T} \frac{d_{1/2}(n)^2}{n}$$

where $d_{1/2}(n)$ is the n th coefficient in the Dirichlet series expansion for $\zeta(s)^{1/2}$ with $\sigma > 1$. Moreover, Heath-Brown's argument in [4] can be adapted to prove that

$$M(T) \leq 3.32 T \sum_{n \leq T} \frac{d_{1/2}(n)^2}{n}.$$

We remark that the sum here is easily evaluated as

$$\sum_{n \leq T} \frac{d_{1/2}(n)^2}{n} \sim c(\log T)^{1/4}$$

with

$$c = \Gamma(5/4)^{-1} \prod_p \left((1 - p^{-1})^{1/4} \sum_{m=0}^{\infty} \left(\frac{\Gamma(m+1/2)}{\Gamma(1/2)m!} \right)^2 p^{-m} \right)$$

where the product is over primes p (and is absolutely convergent).

* Research of both authors partially supported by NSF grants.

While it is known that

$$\int_1^T |\zeta(\sigma + it)| dt \sim T \sum_{n=1}^{\infty} \frac{d_{1/2}(n)^2}{n^{2\sigma}}$$

for $\sigma > 1/2$ (see [7], Section 7.11), the corresponding mean with $\sigma = 1/2$ is elusive. In fact, if $F(s)$ is a function which is representable by a Dirichlet series in some half plane and if $F(s)$ has infinitely many simple zeros on the line $\sigma = \sigma_0$, then no asymptotic formula for

$$\int_1^T |F(\sigma_0 + it)| dt$$

seems to be known.

In this paper we give an example where we can find upper and lower bounds for such a mean where the constants involved are close.

THEOREM. *Let*

$$I(T) = \int_1^T |\zeta(1/2 + it) \zeta'(1/2 + it)| dt.$$

Then, assuming the Riemann Hypothesis,

$$0.53 \dots \lesssim \frac{I(T)}{T \log^2 T} \lesssim 0.57 \dots$$

Remark. The upper constant is $3^{-1/2}$ and it is obtained unconditionally. The lower constant is

$$\left(\frac{1}{4} + \left(\frac{e^2 - 5}{4\pi} \right)^2 \right)^{1/2}.$$

An unconditional lower bound of $1/2$ is essentially trivial.

In Conrey [1] the more complicated example

$$J(T) = \int_1^T |\zeta^3(1/2 + it) \zeta'(1/2 + it)| dt$$

is considered and upper and lower bounds

$$0.02608 \dots \lesssim \frac{J(T)}{T \log^5 T} \lesssim 0.02616 \dots$$

are obtained.

The theorem follows from two lemmas. For the first lemma we recall the function $Z(t)$ from the theory of the Riemann zeta function. It is a real valued function of a real variable such that

$$|Z(t)| = |\zeta(1/2 + it)|.$$

Also, $Z(t)$ changes sign at $t = t_0$ if and only if $1/2 + it_0$ is a zero of $\zeta(s)$ with odd multiplicity. These conditions define $Z(t)$ apart from a plus or minus sign which would not be important here.

LEMMA 1. Assuming the Riemann Hypothesis,

$$\int_1^T |Z(t)Z'(t)| dt \sim \frac{e^2 - 5}{4\pi} T \log^2 T.$$

Proof. Let γ and γ^+ be successive zeros of $Z(t)$ with $0 < \gamma \leq \gamma^+ \leq T$. Then, assuming the Riemann Hypothesis, there is a unique number t_γ in $[\gamma, \gamma^+]$ where $Z'(t_\gamma) = 0$. If $\gamma \leq t \leq t_\gamma$, then $Z(t)Z'(t) \geq 0$ while if $t_\gamma \leq t \leq \gamma^+$, then $Z(t)Z'(t) \leq 0$. Therefore, if γ_0 denotes the least positive zero of $Z(t)$ and γ_T denotes the least zero of $Z(t)$ which is $\geq T$, then

$$\begin{aligned} \int_0^T |Z(t)Z'(t)| dt &= \int_0^{\gamma_0} |ZZ'| + \sum_{0 < \gamma \leq T} \left(\int_\gamma^{t_\gamma} ZZ' - \int_{t_\gamma}^{\gamma^+} ZZ' \right) - \int_T^{\gamma_T} |ZZ'| \\ &= \sum_{0 < \gamma \leq T} \left(\frac{Z(t)^2}{2} \Big|_\gamma^{t_\gamma} - \frac{Z(t)^2}{2} \Big|_{t_\gamma}^{\gamma^+} \right) + O(T^{1/3}) \\ &= \sum_{0 < \gamma \leq T} |Z(t_\gamma)|^2 + O(T^{1/3}) \end{aligned}$$

since

$$|Z(t)Z'(t)| \ll t^{1/3}$$

and

$$|\gamma_T - T| \ll 1.$$

In Conrey and Ghosh [3] we show that, on RH,

$$\sum_{0 < \gamma \leq T} |\zeta(1/2 + it_\gamma)|^2 \sim \frac{e^2 - 5}{4\pi} T \log^2 T.$$

Since $|Z(t)| = |\zeta(1/2 + it)|$, this completes the proof of the lemma.

LEMMA 2. Suppose that $f(x)$ and $g(x)$ are real continuous functions on $[a, b]$, and that

$$\int_a^b f(x) dx \geq \alpha, \quad \int_a^b g(x) dx \geq \beta,$$

where α and β are non-negative. Then

$$\int_a^b |f(x) + ig(x)| dx \geq (\alpha^2 + \beta^2)^{1/2}.$$

Proof. Let

$$F(t) = \int_a^t f(x) dx, \quad G(t) = \int_a^t g(t) dt$$

and suppose that $F(b) = m$ and $G(b) = n$ where $m \geq \alpha$, $n \geq \beta$. Then we require a lower bound for

$$\int_a^b (F'(t)^2 + G'(t)^2)^{1/2} dt$$

where F' and G' are continuous functions with $F(a) = G(a) = 0$, $F(b) = m$, $G(b) = n$. But this integral gives the arc length of the path $p(t) = (F(t), G(t))$ in the plane from $(0, 0)$ to (m, n) . This arc length is clearly not less than the length of the straight line path, which is $(m^2 + n^2)^{1/2}$. The lemma follows.

Proof of theorem. For the upper bound we have by the Cauchy-Schwarz inequality (see Ingham [5] for the second moment of ζ'),

$$I(T) \leq \left(\int_1^T |\zeta(1/2+it)|^2 dt \right)^{1/2} \left(\int_1^T |\zeta'(1/2+it)|^2 dt \right)^{1/2} \\ \sim (T \log T)^{1/2} \left(\frac{1}{3} T \log^2 T \right)^{1/2} = 3^{-1/2} T \log^2 T.$$

For the lower bound, we make use of the fact that

$$\operatorname{Re} \frac{\zeta'}{\zeta}(1/2+it) \sim -\frac{1}{2} \log t,$$

whence follows easily

$$(1) \quad \int_1^T |\zeta(1/2+it)|^2 \left| \operatorname{Re} \frac{\zeta'}{\zeta}(1/2+it) \right| dt \sim \frac{T}{2} \log^2 T.$$

This leads to the "trivial" lower bound, since

$$(2) \quad I(T) = \int_1^T |\zeta(1/2+it)|^2 \left| \operatorname{Re} \frac{\zeta'}{\zeta}(1/2+it) + i \operatorname{Im} \frac{\zeta'}{\zeta}(1/2+it) \right| dt$$

is clearly greater than or equal to the integral in (1). We observe that by the properties of $Z(t)$,

$$\zeta(1/2+it) = Z(t) e^{i\vartheta(t)}$$

where $\vartheta(t)$ is a real valued function of t . Then

$$i \frac{\zeta'}{\zeta}(1/2+it) = \frac{Z'}{Z}(t) + i\vartheta'(t)$$

so that

$$\frac{Z'}{Z}(t) = -\operatorname{Im} \frac{\zeta'}{\zeta}(1/2 + it).$$

Thus,

$$(3) \quad \int_1^T |\zeta(1/2 + it)|^2 \left| \operatorname{Im} \frac{\zeta'}{\zeta}(1/2 + it) \right| dt = \int_1^T |Z(t) Z'(t)| dt \sim \frac{e^2 - 5}{4\pi} T \log^2 T$$

by Lemma 1.

The theorem now follows from (1), (2), (3) and Lemma 2.
